1 Issue 2 (PRINT-READ consistency)

1.1 Description

Lisp reader uses `find-package` when reading a symbol, which is affected by the *local nicknames* of the *current package*. That means that to maintain **print-read** consistency when printing a symbol, a good *package prefix* must be used - such that calling `find-package` on it in the *current package* returns the symbol's *home package*.

There are several situations to consider:

1. Symbol is *apparently uninterned*.

   In this case it must be printed without any package prefix, preceeded by `#:`.

2. Symbol is accessible in the *current package*.

   In this case it must be printed without any package prefix.

3. Symbol's *home package name* or one of its *global nicknames* is not shadowed by any *local nickname* defined in the *current package*.

   In this case that name or global nickname can be used as the package prefix.

4. There **exists** a *local nickname* defined in the *current package* for the symbol's *home package*.

   In this case that local nickname can be used as the package prefix.

5. Symbol's *home package name* and all of its *global nicknames* are shadowed by the *local nicknames* of the *current package* and there **is no** *local nickname* defined in the *current package* for the symbol's *home package*.

   It is not clear how the symbol must be printed, see PROPOSALS.

1.2 Examples

```
(defpackage #:foo
  (:use)
  (:export #:+))

(defpackage #:bar
  (:use #:cl)
  (:local-nicknames (#:foo #:cl)))
```

```
(let ((*package* (find-package '#:bar)))
  (print 'foo:+))
; >> FOO:+  (sbcl, ccl, ecl, acl, abcl, clasp, lispworks)

;; In the package #:BAR symbol FOO:+ refers to CL:+

(defpackage #:foo-a (:use) (:export #:quux))
(defpackage #:foo-b (:use) (:export #:quux))

(defpackage #:bar
  (:use)
  (:local-nicknames (#:foo-a #:foo-b)
                    (#:foo-b #:foo-a)))

(let ((*package* (find-package '#:bar)))
  (print 'foo-a:quux))
; >> FOO-B:QUUX  (sbcl, ccl, abcl, lispworks)
; >> FOO-A:QUUX  (ecl, acl, clasp)

;; In the package #:BAR symbol FOO-A:QUUX refers to FOO-B:QUUX
```

1.3 Current behavior

sbcl, ccl, abcl, lispworks: When exists in the *current package*, a *local nickname* is used as a package prefix when printing a symbol.

ecl, acl, clasp: *local nickname* is never used as a package prefix when printing a symbol.

1.4 Proposal SHARPSIGN-DOT

In the case (5) the symbol must be printed using the `#.` syntax:

```
#.(cl:let ((cl:*package* (cl:find-package "KEYWORD")))
    (cl:find-symbol "BAR" "FOO"))
;; or
#.(cl:let ((cl:*package* (cl:find-package "KEYWORD")))
    (cl:intern "BAR" "FOO"))
```

Note that `#:KEYWORD` name is reserved for the `#:KEYWORD` package and cannot be used as a *local nickname* thus this expression will always evaluate to the symbol `foo::bar`.

If `*read-eval*` is *false* and `*print-readably*` is *true* an error of type `print-not-readable` must be signalled.

1.5 Proposal SHARPSIGN-COLON

In case (5) the symbol should be printed using the *extended `#:` syntax*:

```
#:(package name)
#::(package name)
```

Shinmera's idea.

1.6 Proposal SHARPSIGN-BACKQUOTE

In case (5) the symbol must be printed using the new `#‘` syntax for reading an expression ignoring *local nicknames* in the *current package*:

```
#‘foo:bar
#‘foo::bar
```

It can be implemented roughly as follows:

```
(defun |#‘-reader| (stream subchar arg)
  (declare (ignore subchar arg))
  (let* ((current-package *package*)
         (local-nicknames (package-local-nicknames current-package)))
    (loop for (nick . package) in local-nicknames
          do (remove-package-local-nickname nick current-package))
    (unwind-protect
      (read stream t nil t)
      (loop for (nick . package) in local-nicknames
            do (add-package-local-nickname nick package current-package)))))

(set-dispatch-macro-character #\# #\‘ #’|#‘-reader|)
```

It is *implementation-dependent* whether *local nicknames* are actually removed from the *current package* or not.

1.7 Proposal PRINT-UNREADABLY

In the case (5) the symbol must be printed unreadably using the `#<` syntax:

```
#<SYMBOL IN THE SHADOWED PACKAGE FOO:BAR>
#<SYMBOL IN THE SHADOWED PACKAGE FOO::BAR>
```

(Specifics are *implementation-dependent*.)
If `*print-readably*` is *true*, an error of type `print-not-readable` must be signalled.

1.8 Proposal THREE-FOUR-PACKAGE-MARKERS

In the case (5) the symbol must be printed using `:::` and `::::` syntax as follows:

```
foo:::bar   ; same as (cl:find-symbol "BAR" "FOO") in the #:KEYWORD package
foo::::bar  ; same as (cl:intern "BAR" "FOO") in #:KEYWORD package
```
